

GitHub/Spec-kit

<https://github.com/github/spec-kit> is a toolkit that extends code agents with PRD editing capabilities. It is particularly relevant to the method we want to adopt in our project and I recommend you use it, although you can work without it as well if you work out how to prompt the LLM to perform the requested tasks.

`spec-kit` introduces spec-specific commands such as:

- `/speckit.constitution` Create principles focused on code quality, testing standards, user experience consistency, and performance requirements
- `/speckit.specify` Build an application that can help me organize my photos in separate photo albums. Albums are grouped by date and can be re-organized by dragging and dropping on the main page. Albums are never in other nested albums. Within each album, photos are previewed in a tile-like interface.
- `/speckit.plan` The application uses Vite with minimal number of libraries. Use vanilla HTML, CSS, and JavaScript as much as possible. Images are not uploaded anywhere and metadata is stored in a local SQLite database.

Additional commands are available to manipulate specifications and break them down into tasks and implementation artifacts.

Command	Description
<code>/speckit.tasks</code>	Creates an actionable task list from your implementation plan.
<code>/speckit.clarify</code>	Clarify underspecified areas (recommended before <code>/speckit.plan</code>)
<code>/speckit.analyze</code>	Cross-artifact consistency & coverage analysis (run after <code>/speckit.tasks</code> , before <code>/speckit.implement</code>)
<code>/speckit.checklist</code>	Generate custom quality checklists that validate requirements completeness, clarity, and consistency (like "unit tests for English")
<code>/speckit.implement</code>	to execute all tasks and build your feature according to the plan.
